

Week 4X, 2018

Principal Component Analysis and Eigenfaces

Daniel Merkle

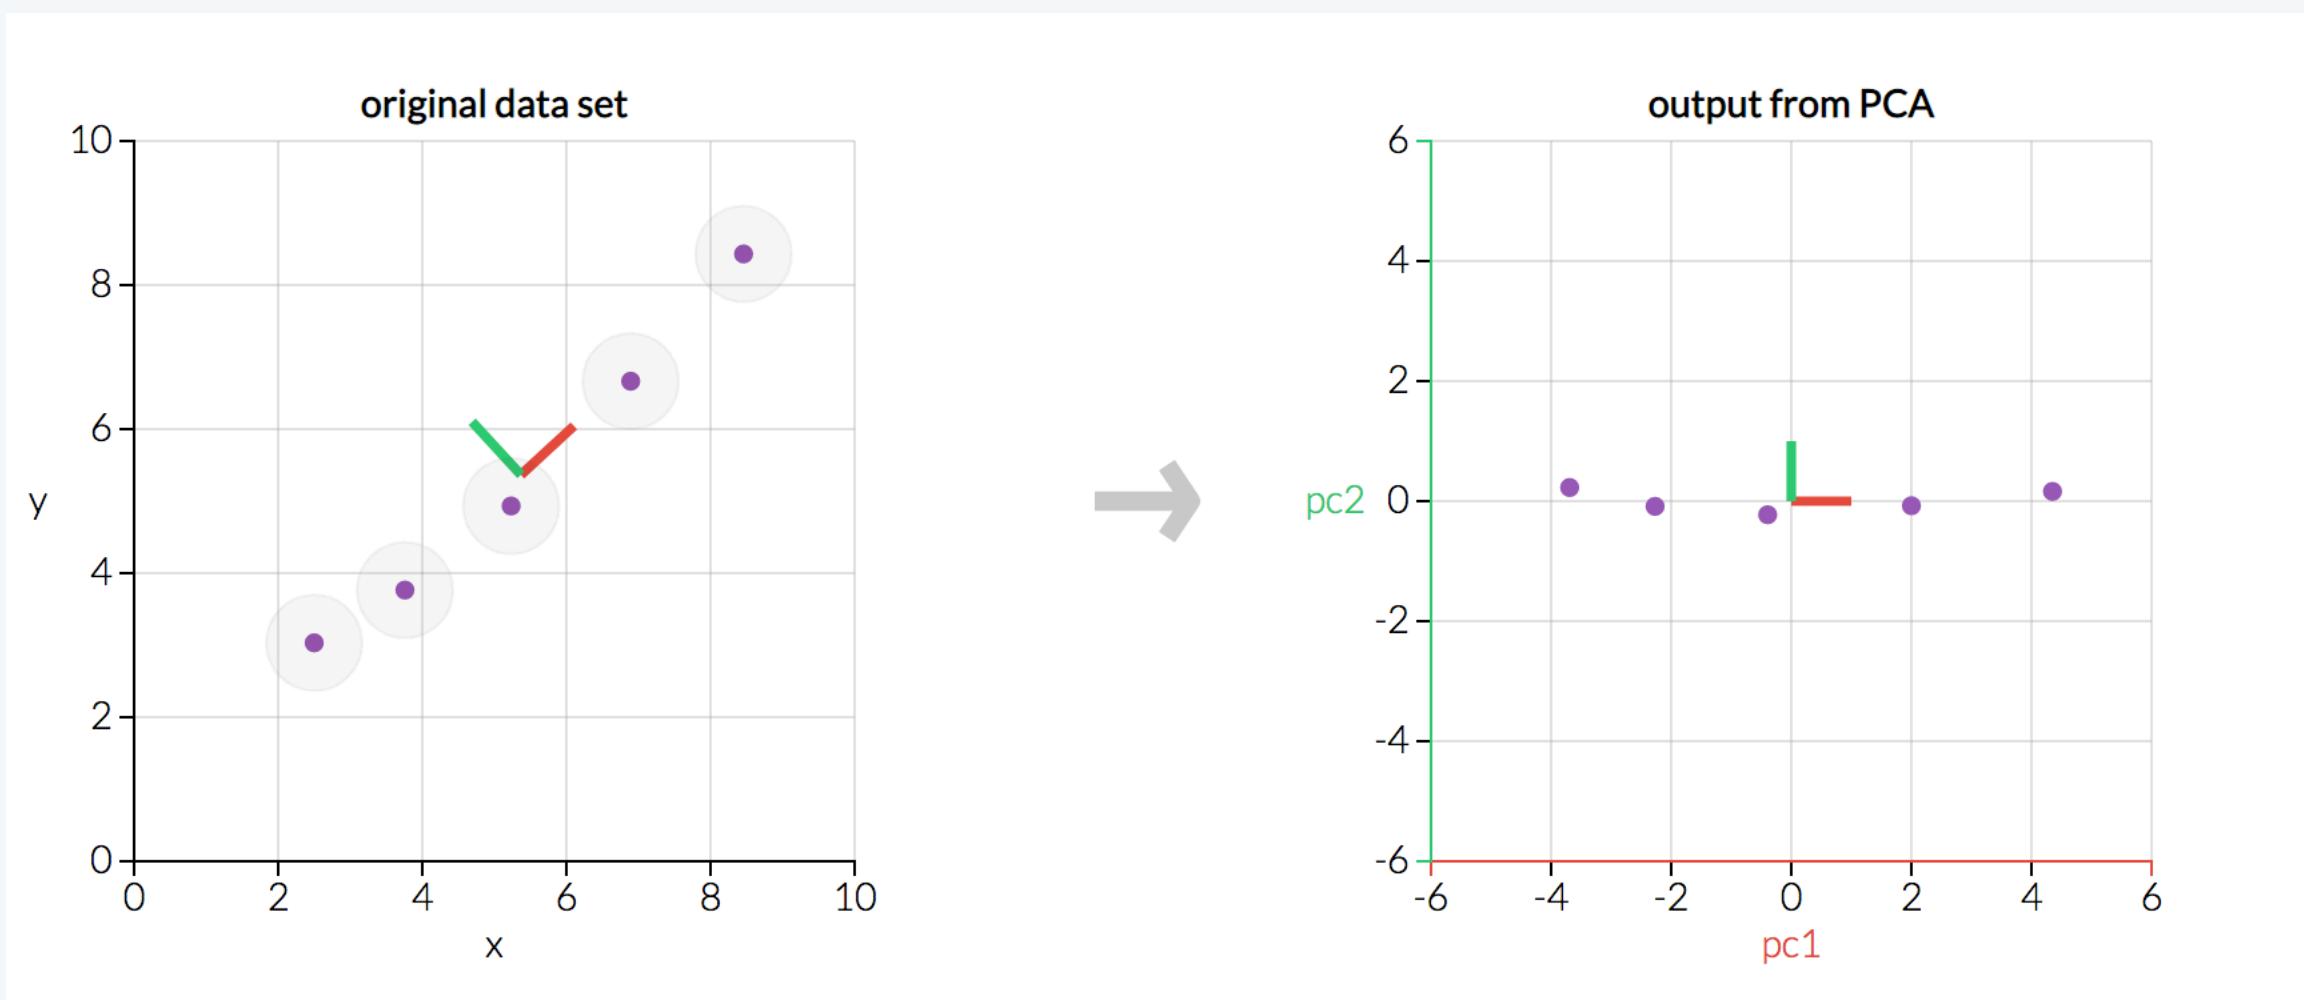

daniel@imada.sdu.dk

Introduction and Motivational Example

- PCA is considered the “**the mother of all methods in multivariate data analysis**”
- Dimensionality reduction
- Exploit linear dependencies in data
- PCA can be seen as a method to compute a **new coordinate system** formed by latent* variables, which is **orthogonal**, and where only the **most informative dimensions** are used.
- Dimension reduction by PCA is mainly used for
 - Visualization of multivariate data
 - Transformation of highly correlating variables into a smaller set of uncorrelated
 - Separation of relevant information from noise
 - Combination of several variables that characterize a chemical-technological process

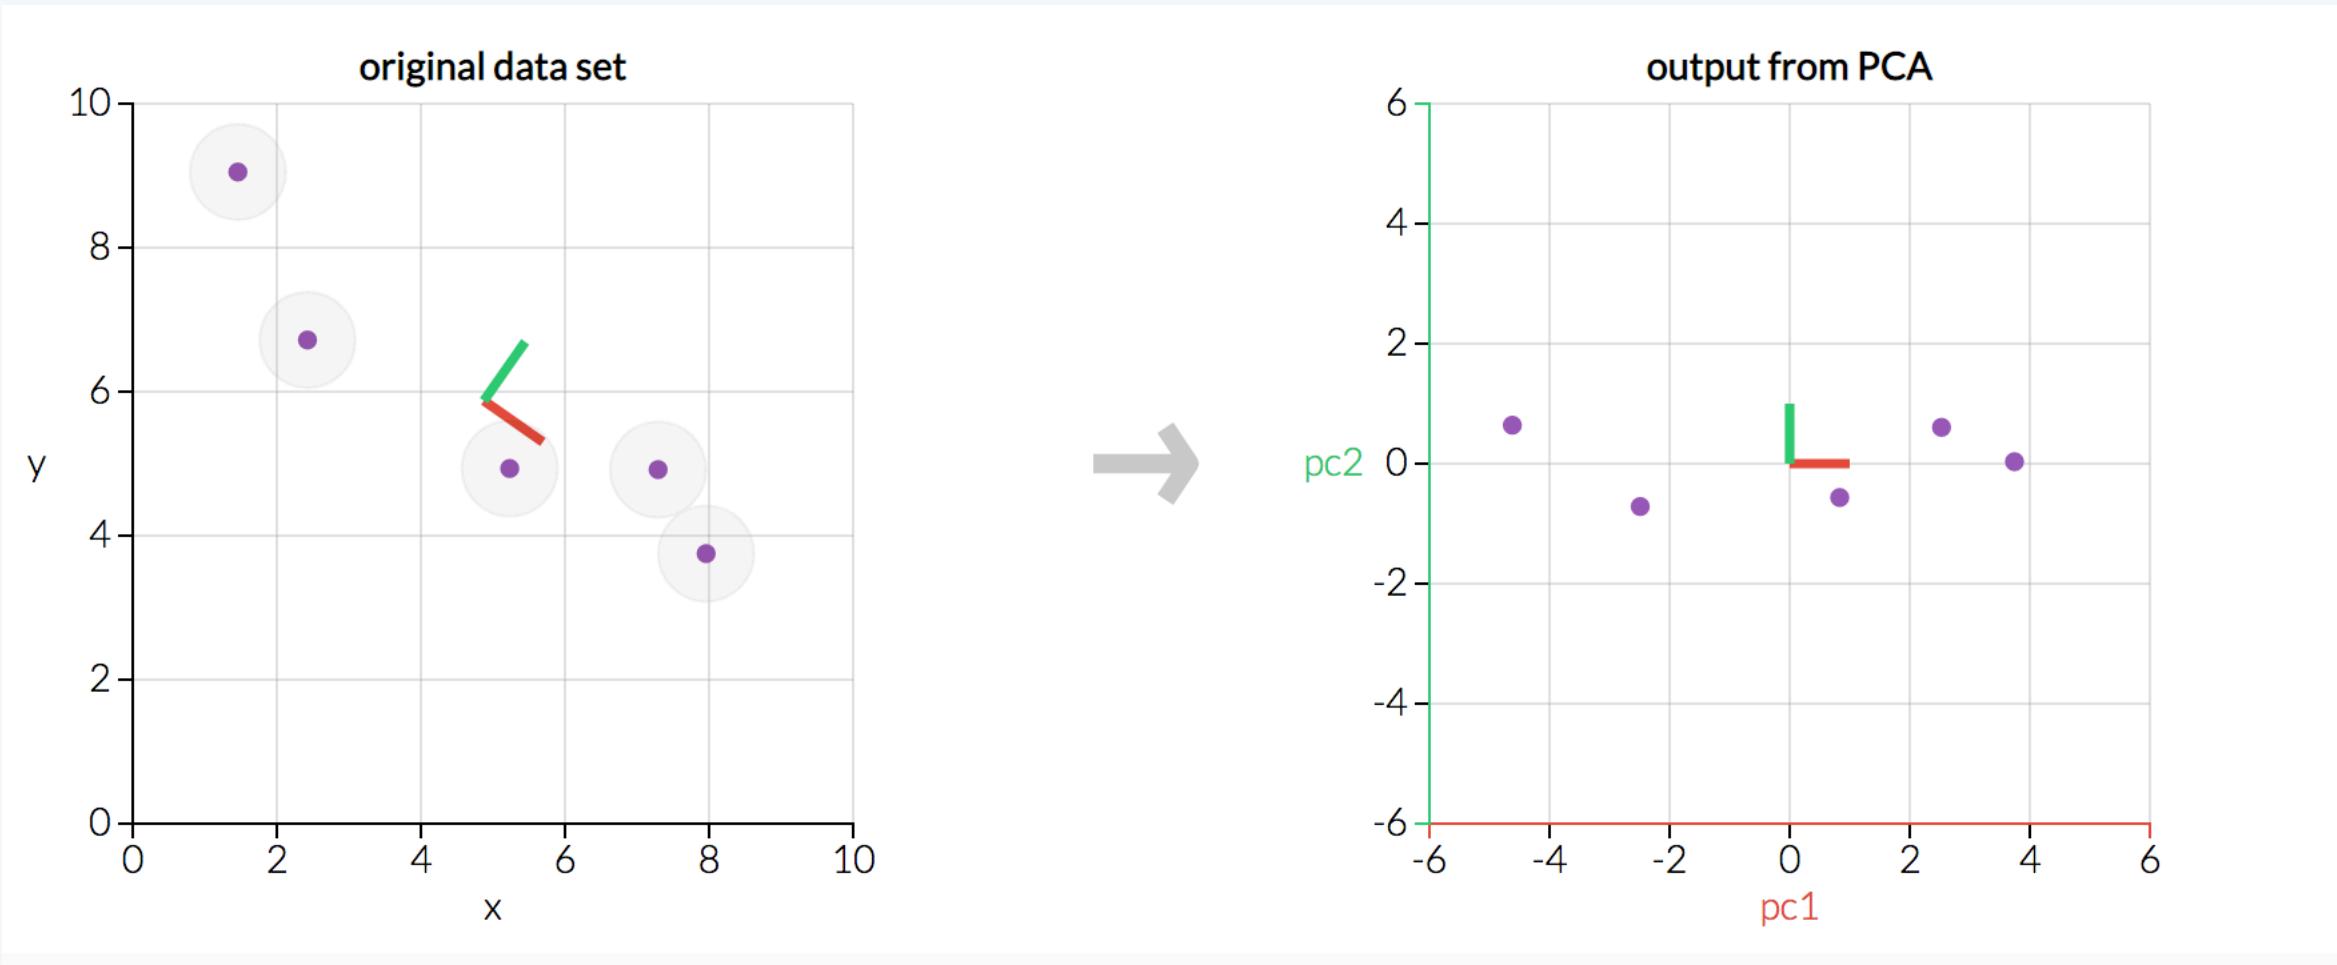

*variables that are not directly observed but are rather inferred (through a mathematical model)

PCA finds a new coordinate system

Nice visualization : <http://setosa.io/ev/principal-component-analysis/>

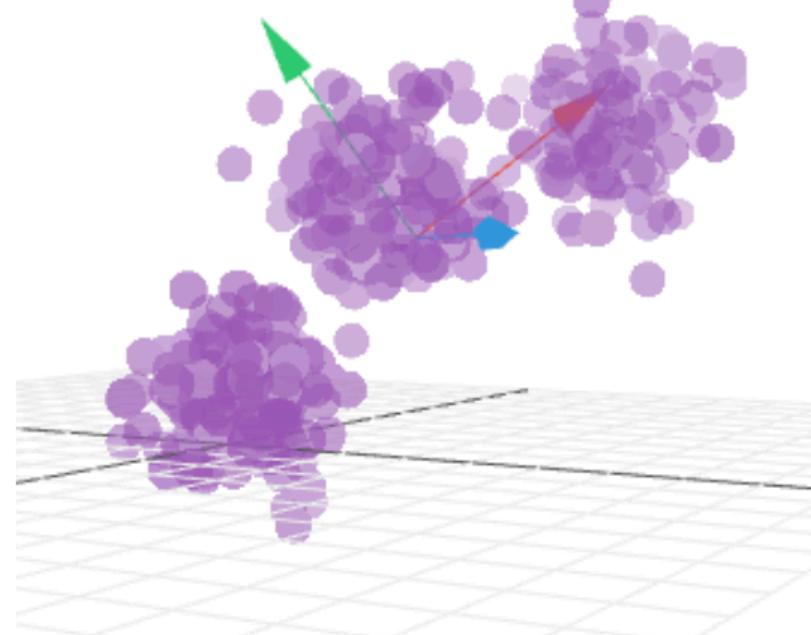

New Dimensions are called Principal Components

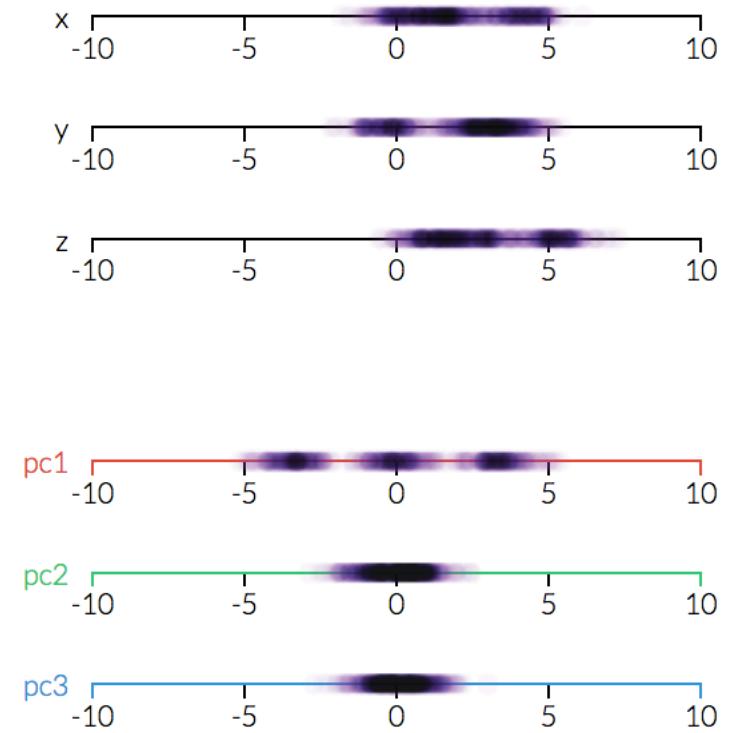

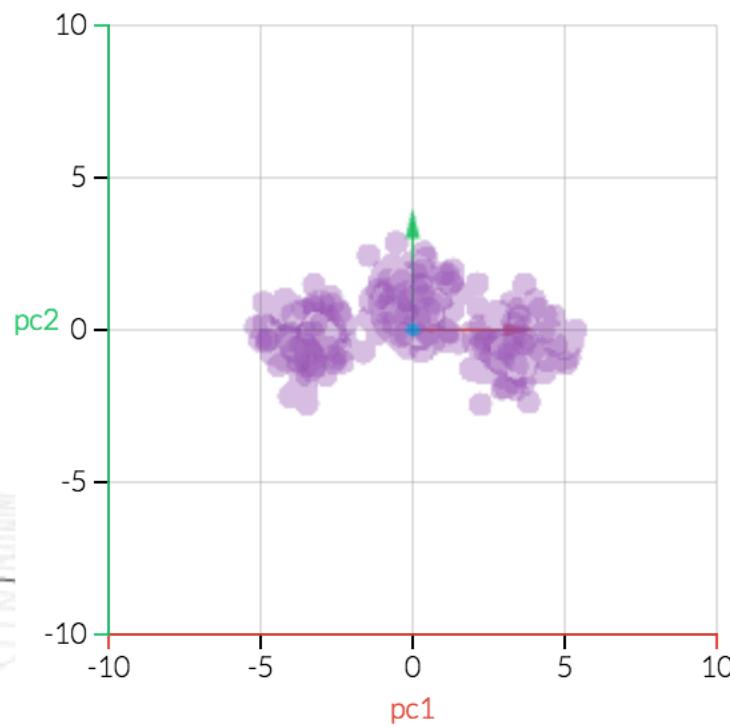

This transformation is defined in such a way that the **first principal component has the largest possible variance** (that is, accounts for as much of the variability in the data as possible), and **each succeeding component in turn** has the highest variance possible under the constraint that it is **orthogonal** to the preceding components.

Dimensionality Reduction

Original (observed) data

Projected data

Mathematical Background

- Orthogonal Basis
- Linear Transformation
- Covariance Matrix
- And (we will use without proof):
 - The inverse of an orthonormal matrix is its transpose (1)
 - For any matrix A , $A^T A$ and $A A^T$ are symmetric.
 - A matrix is symmetric if and only if it is orthogonally diagonalizable.
 - A symmetric matrix is diagonalized by a matrix of its orthonormal eigenvectors, i.e., for any squared symmetric matrix A , there exists a diagonal matrix D , such that $A = E D E^T$, where the i -th column of E is the i -th eigenvector of A (special case of an **SVD decomposition**). The orthonormal column vectors of E span a space, and due to (1) $E^{-1} = E^T$

Change of Basis – Linear Transformation

[Presented on blackboard. More details : page 3 of *A Tutorial on Principal Component Analysis* (Jonathon Shlens)]

Original data: X ($m \times n$ matrix)

P is the matrix that transforms X into Y

Y ($m \times n$ matrix) is the new representation of the data set

$$Y = PX$$

The rows of P are the new basis vectors

Mathematical Prerequisites - Covariance

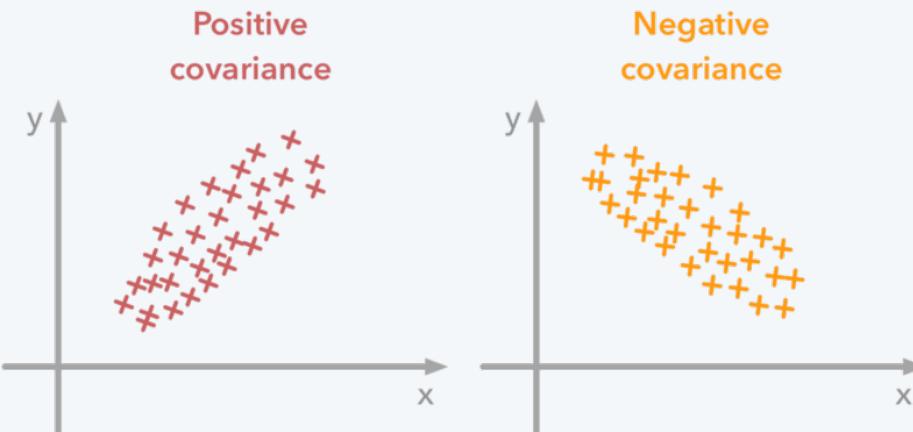

$$A = \{a_1, \dots, a_n\}$$

$$B = \{b_1, \dots, b_n\}$$

$$\text{cov}(A, B) = \sigma_{AB}^2 = \frac{1}{n} \sum_{i=1}^n (a_i - \bar{a})(b_i - \bar{b})$$

Assuming A and B are mean centered:

$$\sigma_{AB}^2 = \frac{1}{n} \sum_{i=1}^n a_i b_i$$

Assuming (mean-centered) row vectors for a and b:

$$\mathbf{a} = (a_1, \dots, a_n)$$
$$\mathbf{b} = (b_1, \dots, b_n)$$
$$\sigma_{ab}^2 = \frac{1}{n} \mathbf{a} \mathbf{b}$$

Covariance Matrix

Assume data (m types of measurements) given as

$$X = \begin{bmatrix} \mathbf{x}_1 \\ \vdots \\ \mathbf{x}_m \end{bmatrix}$$

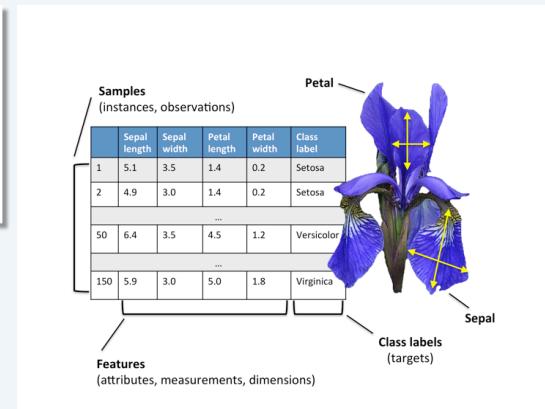

A note of caution, sometimes the role of column and row (type of measurement/samples) is switched.
Obviously, then:

$$X = [\mathbf{x}_1 \dots \mathbf{x}_m]$$

$$C_X = \frac{1}{n} X^T X$$

	sepal_len	sepal_wid	petal_len	petal_wid	class
145	6.7	3.0	5.2	2.3	Iris-virginica
146	6.3	2.5	5.0	1.9	Iris-virginica
147	6.5	3.0	5.2	2.0	Iris-virginica
148	6.2	3.4	5.4	2.3	Iris-virginica
149	5.9	3.0	5.1	1.8	Iris-virginica

Data given as a matrix of size
samples x features
 $m \times n$
 150×4

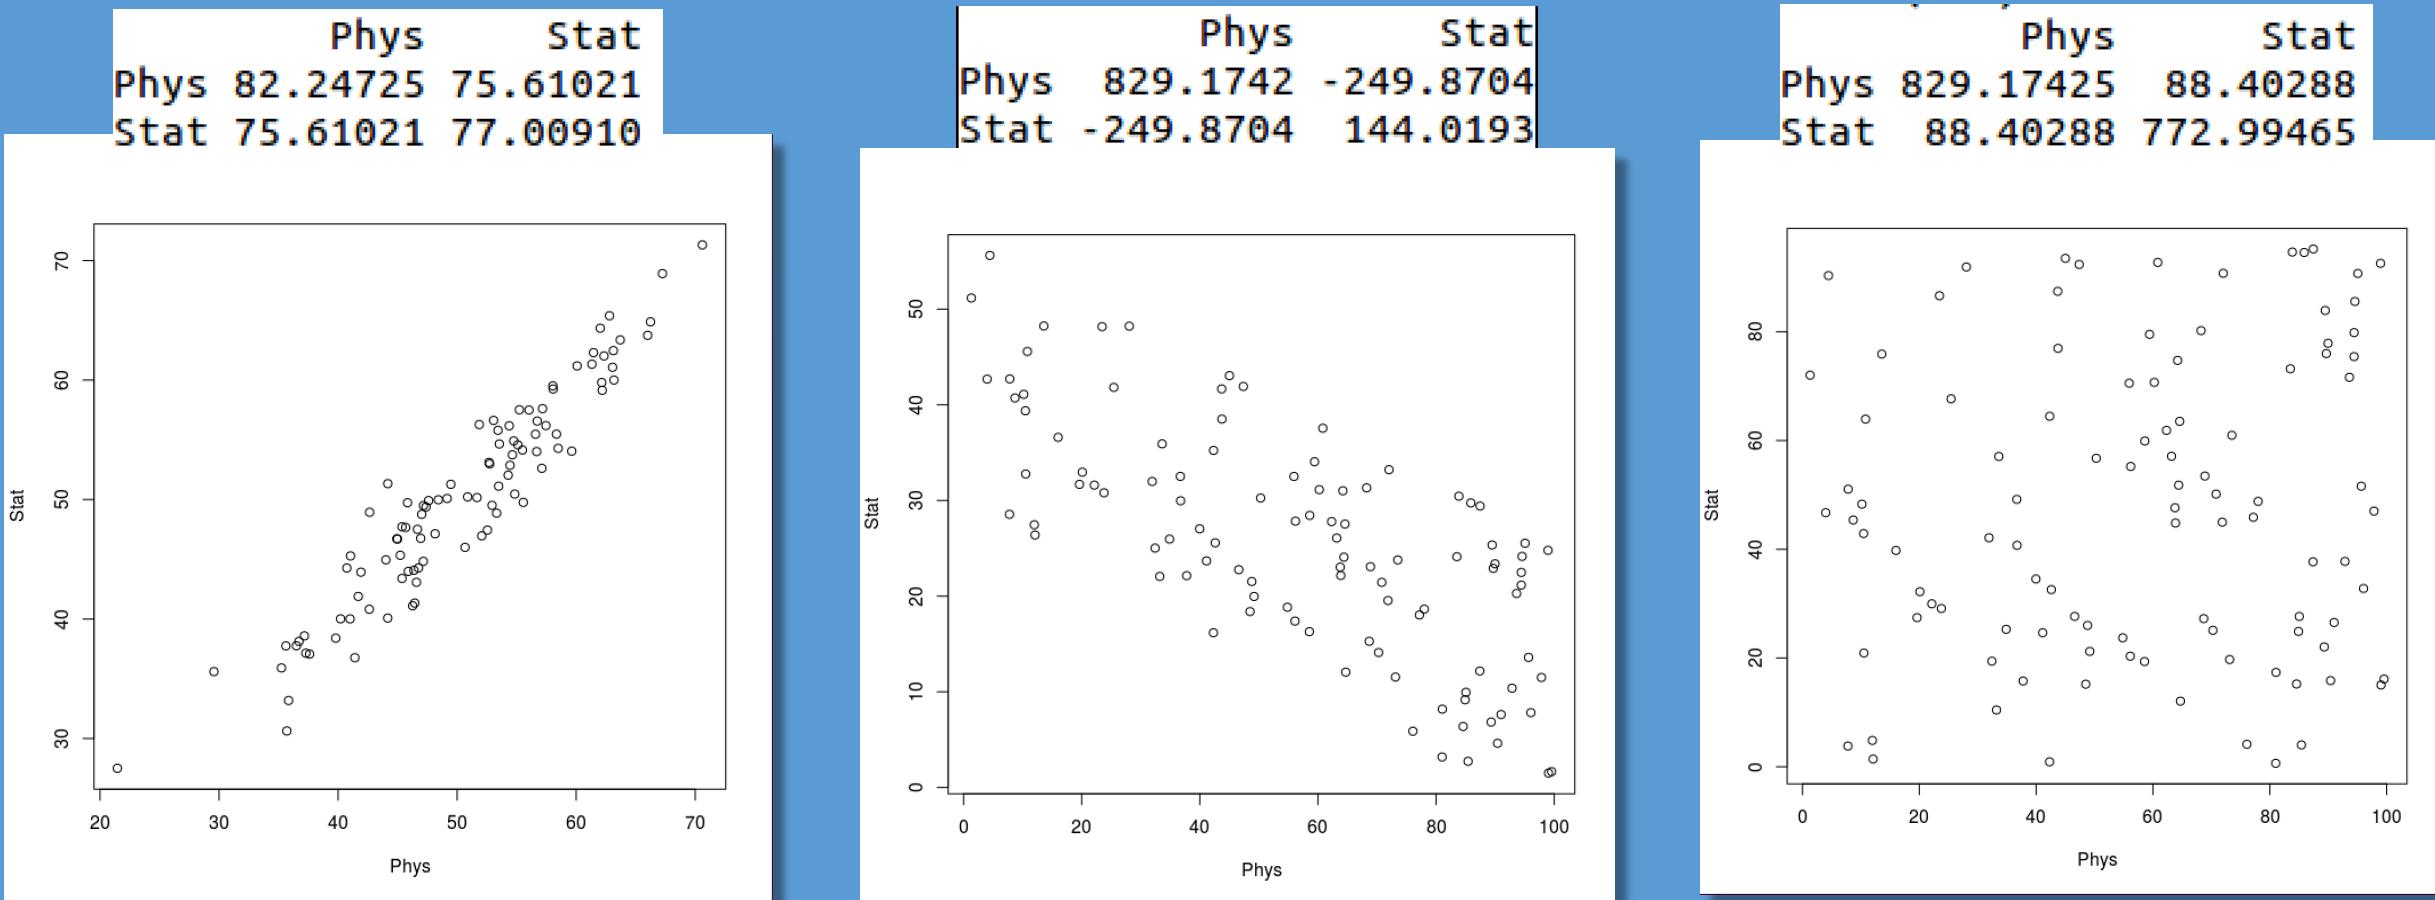

Each **row** of X corresponds to all m measurements of a particular type. Each **column** of X corresponds to a set of all n measurements from one particular trial.

Covariance Matrix : $C_X = \frac{1}{n} X X^T$

captures the covariance between all possible pairs of measurements. The covariance values reflect the noise and redundancy in our measurements.

Properties of the Covariance Matrix

- C_X is a square symmetric $m \times m$ matrix (m is the number of features)
- The diagonal terms of C_X are the *variance* of particular measurement types.
- The off-diagonal terms of C_X are the *covariance* between measurement types.

Example: Physics and Statistics grade [0-100 points], measured for 100 students

Iris Example (150 samples, 50 from 3 different species)

https://en.wikipedia.org/wiki/Iris_flower_data_set

	sepal_len	sepal_wid	petal_len	petal_wid	class
145	6.7	3.0	5.2	2.3	Iris-virginica
146	6.3	2.5	5.0	1.9	Iris-virginica
147	6.5	3.0	5.2	2.0	Iris-virginica
148	6.2	3.4	5.4	2.3	Iris-virginica
149	5.9	3.0	5.1	1.8	Iris-virginica

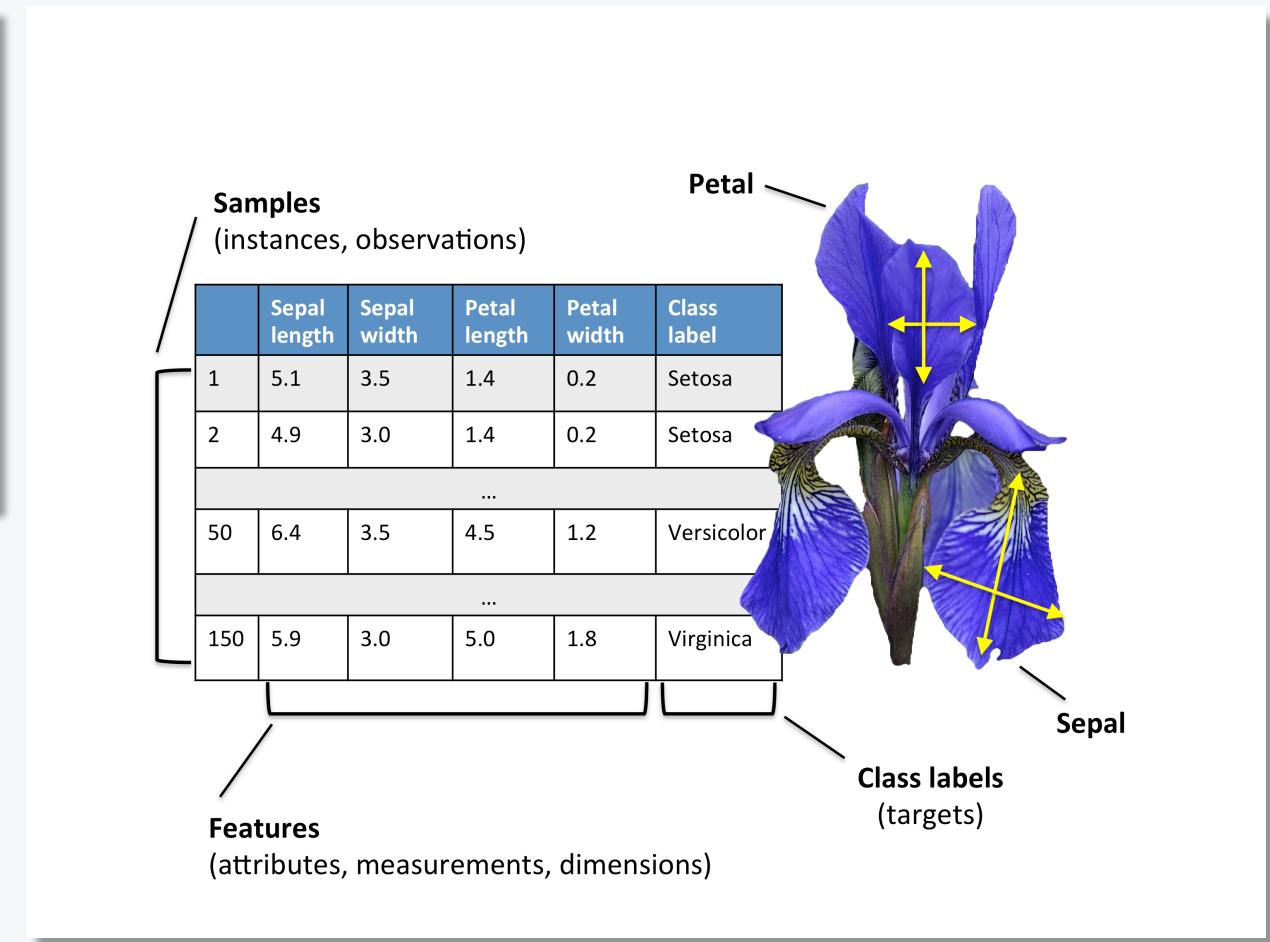

Data given as a matrix of size
samples x features

$n \times m$

150 x 4

$$X = [\mathbf{x}_1 \dots \mathbf{x}_m]$$

$$C_X = \frac{1}{n} X^T X$$

Question!

Pretend we have the option of manipulating the covariance matrix C_X (by a change of basis such that X will be transformed into Y , i.e., $Y = PX$). We will define our manipulated covariance matrix C_Y . What features do we ideally want to have in C_Y ?

- All off-diagonal terms in C_Y should be zero. Thus, **C_Y must be a diagonal matrix.** Or, said another way, Y is de-correlated.
- Each successive **dimension in Y** should be **rank-ordered** according to variance.

Can we find some orthonormal matrix P in $Y = PX$ such that

$$C_Y = \frac{1}{n} YY^T$$

is a diagonal matrix?

YES!

[Presented on blackboard. More details : page 3 of *A Tutorial on Principal Component Analysis* (Jonathon Shlens)]

$$\begin{aligned}\mathbf{C}_Y &= \frac{1}{n} \mathbf{Y} \mathbf{Y}^T \\ &= \frac{1}{n} (\mathbf{P} \mathbf{X}) (\mathbf{P} \mathbf{X})^T \\ &= \frac{1}{n} \mathbf{P} \mathbf{X} \mathbf{X}^T \mathbf{P}^T \\ &= \mathbf{P} \left(\frac{1}{n} \mathbf{X} \mathbf{X}^T \right) \mathbf{P}^T \\ \mathbf{C}_Y &= \mathbf{P} \mathbf{C}_X \mathbf{P}^T\end{aligned}$$

We select the matrix P to be a matrix where each row p_i is an eigenvector of $\frac{1}{n} \mathbf{X} \mathbf{X}^T$, i.e., $P = E^T$

$$\begin{aligned}C_Y &= P \cdot C_X \cdot P^T \\ &= P \cdot E \cdot D \cdot E^T \cdot P \\ &= E^T \cdot E \cdot D \cdot E^T \cdot E \\ &= E^{-1} \cdot E \cdot D \cdot E^{-1} \cdot E \\ &= D\end{aligned}$$

PCA in Python (numpy only)

```
# principal component analysis
from numpy import array
from numpy import mean
from numpy import cov
from numpy.linalg import eig
# define matrix
A = array([
    [1, 2],
    [3, 4],
    [5, 6]])
print(A)
# column means
M = mean(A.T, axis=1)
# center columns by subtracting column means
C = A - M
# calculate covariance matrix of centered matrix
V = cov(C.T)
# factorize covariance matrix
values, vectors = eig(V)
print(vectors)
print(values)
# project data
P = vectors.T.dot(C.T)
print(P.T)
```

Iris Dataset - Exploratory Visualization (https://en.wikipedia.org/wiki/Iris_flower_data_set)

https://sebastianraschka.com/Articles/2015_pca_in_3_steps.html

```
from matplotlib import pyplot as plt
import numpy as np
import math

label_dict = {1: 'Iris-Setosa',
              2: 'Iris-Versicolor',
              3: 'Iris-Virginica'}

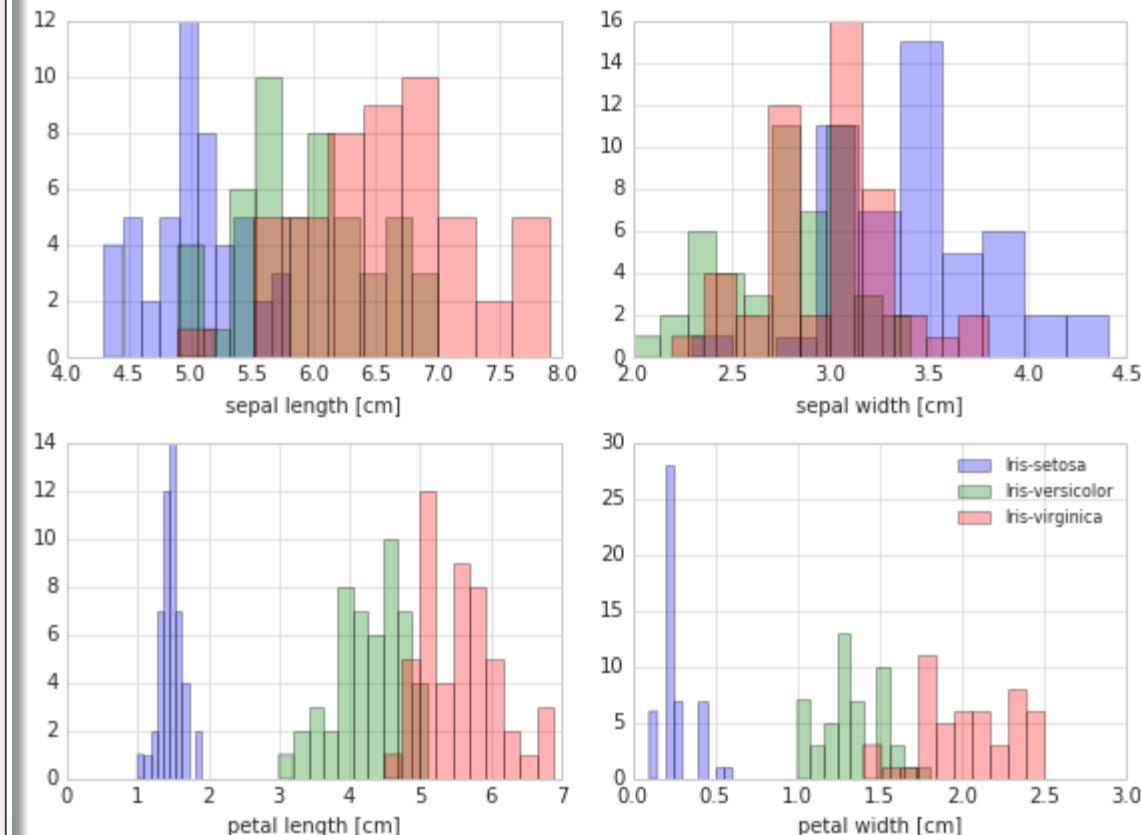

feature_dict = {0: 'sepal length [cm]',
                1: 'sepal width [cm]',
                2: 'petal length [cm]',
                3: 'petal width [cm]'}

with plt.style.context('seaborn-whitegrid'):
    plt.figure(figsize=(8, 6))
    for cnt in range(4):
        plt.subplot(2, 2, cnt+1)
        for lab in ('Iris-setosa', 'Iris-versicolor', 'Iris-virginica'):
            plt.hist(X[y==lab, cnt],
                      label=lab,
                      bins=10,
                      alpha=0.3)
        plt.xlabel(feature_dict[cnt])
        plt.legend(loc='upper right', fancybox=True, fontsize=8)

    plt.tight_layout()
    plt.show()
```

The three classes in the Iris dataset are:

Iris-setosa (n=50), blue
Iris-versicolor (n=50), green
Iris-virginica (n=50), red

Standardizing:

Since PCA yields a feature subspace that maximizes the variance along the axes, it makes (often) sense to standardize the data, especially, if it was measured on different scales. -> mean 0, variance 1

```
from sklearn.preprocessing import StandardScaler  
X_std = StandardScaler().fit_transform(X)
```

Covariance Matrix:

```
import numpy as np  
mean_vec = np.mean(X_std, axis=0)  
cov_mat = (X_std - mean_vec).T.dot((X_std - mean_vec)) / (X_std.shape[0]-1)  
print('Covariance matrix \n%s' %cov_mat)
```

```
Covariance matrix  
[[ 1.00671141 -0.11010327  0.87760486  0.82344326]  
 [-0.11010327  1.00671141 -0.42333835 -0.358937 ]  
 [ 0.87760486 -0.42333835  1.00671141  0.96921855]  
 [ 0.82344326 -0.358937     0.96921855  1.00671141]]
```

Diagonal not 1? -> Bessel

Eigenvectors (the Principal Components, see matrix P of the transformation)

```
cov_mat = np.cov(X_std.T)

eig_vals, eig_vecs = np.linalg.eig(cov_mat)

print('Eigenvectors \n%s' %eig_vecs)
print('\nEigenvalues \n%s' %eig_vals)
```

Eigenvectors

```
[[ 0.52237162 -0.37231836 -0.72101681  0.26199559]
 [-0.26335492 -0.92555649  0.24203288 -0.12413481]
 [ 0.58125401 -0.02109478  0.14089226 -0.80115427]
 [ 0.56561105 -0.06541577  0.6338014   0.52354627]]
```

Eigenvalues

```
[ 2.93035378  0.92740362  0.14834223  0.02074601]
```

Another note of caution:

$v : (..., M, M) \text{array}$

The normalized (unit “length”) eigenvectors, such that the column $v[:, i]$ is the eigenvector corresponding to the eigenvalue $w[i]$.

Sorting Eigenvectors

```
# Make a list of (eigenvalue, eigenvector) tuples
eig_pairs = [(np.abs(eig_vals[i]), eig_vecs[:,i]) for i in range(len(eig_vals))]

# Sort the (eigenvalue, eigenvector) tuples from high to low
eig_pairs.sort(key=lambda x: x[0], reverse=True)

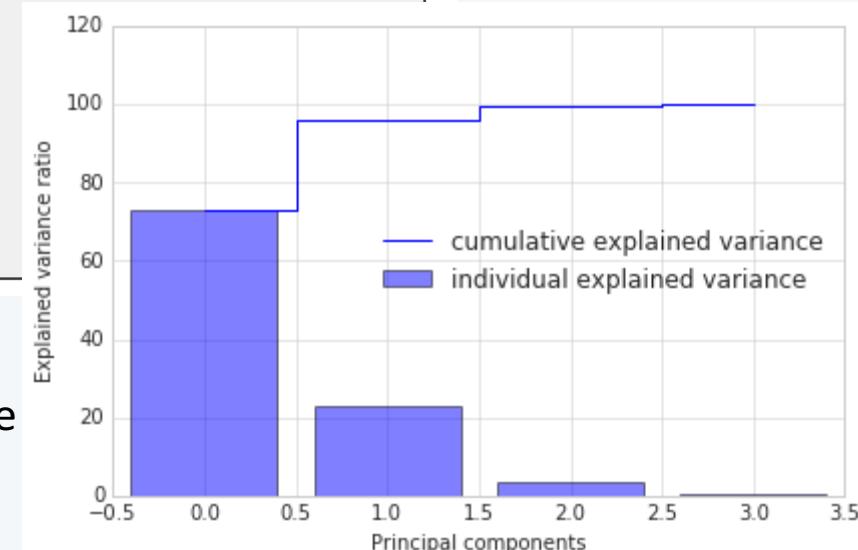

# Visually confirm that the list is correctly sorted by decreasing eigenvalues
print('Eigenvalues in descending order:')

for i in eig_pairs:
    print(i[0])
```

Eigenvalues in descending order:

2.91081808375
0.921220930707
0.147353278305
0.0206077072356

Explained variance in dataset: The first two principal components contain 95.8% of the information.

Projection onto the new feature space

Here, we are reducing the 4-dimensional feature space to a 2-dimensional feature subspace, by choosing the “top 2” eigenvectors

```
matrix_w = np.hstack((eig_pairs[0][1].reshape(4,1),
                      eig_pairs[1][1].reshape(4,1)))

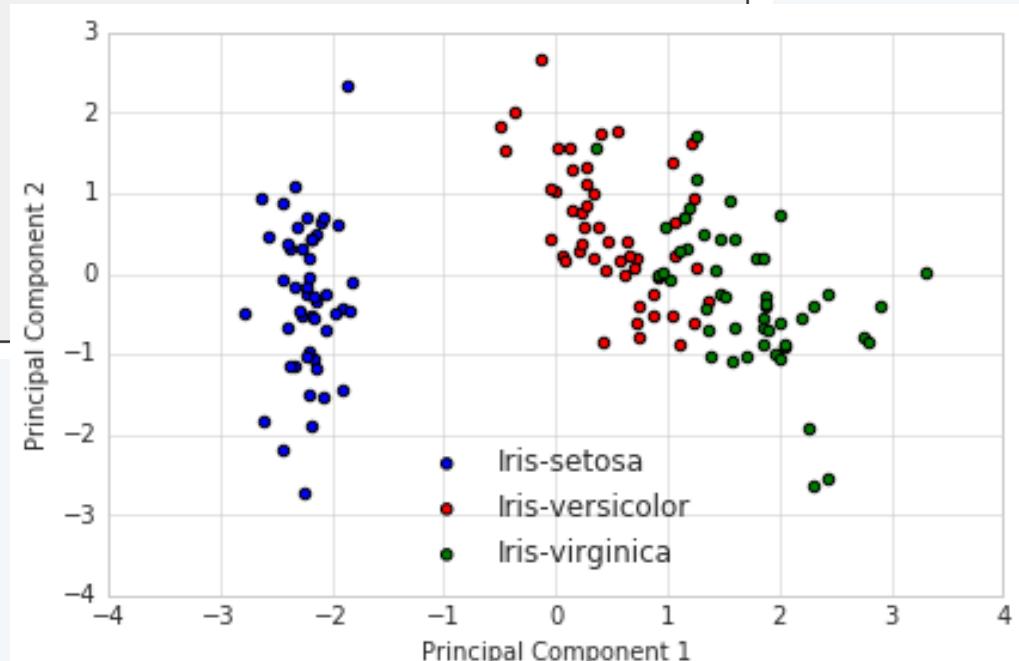

print('Matrix W:\n', matrix_w)
```

```
Matrix W:
[[ 0.52237162 -0.37231836]
 [-0.26335492 -0.92555649]
 [ 0.58125401 -0.02109478]
 [ 0.56561105 -0.06541577]]
```

Projection onto the new feature space:

```
y = X_std.dot(matrix_w)
```

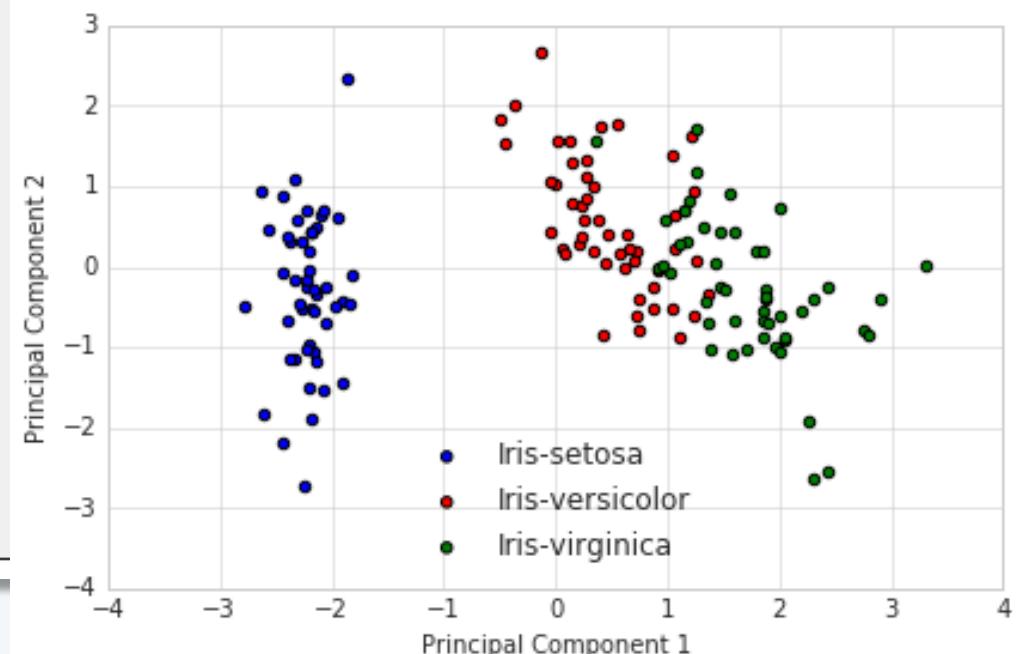

```
with plt.style.context('seaborn-whitegrid'):
    plt.figure(figsize=(6, 4))
    for lab, col in zip(('Iris-setosa', 'Iris-versicolor', 'Iris-virginica'),
                         ('blue', 'red', 'green')):
        plt.scatter(Y[y==lab, 0],
                    Y[y==lab, 1],
                    label=lab,
                    c=col)
    plt.xlabel('Principal Component 1')
    plt.ylabel('Principal Component 2')
    plt.legend(loc='lower center')
    plt.tight_layout()
    plt.show()
```

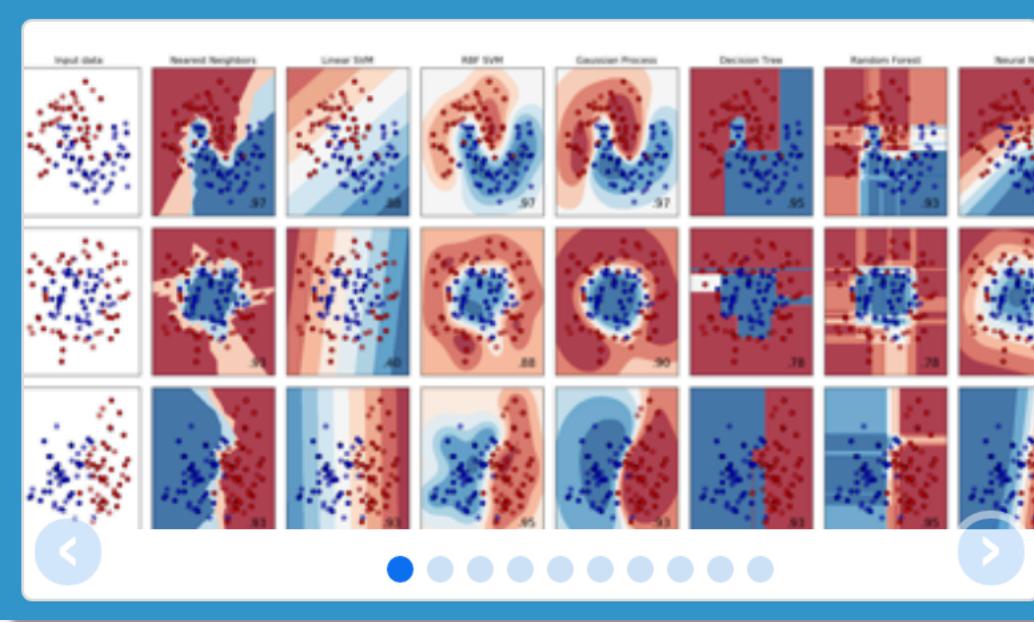

All in one go (here: `sklearn`)

```
from sklearn.decomposition import PCA as sklearnPCA  
sklearn_pca = sklearnPCA(n_components=2)  
Y_sklearn = sklearn_pca.fit_transform(X_std)
```

```
with plt.style.context('seaborn-whitegrid'):  
    plt.figure(figsize=(6, 4))  
    for lab, col in zip(('Iris-setosa', 'Iris-versicolor', 'Iris-virginica'),  
                        ('blue', 'red', 'green')):  
        plt.scatter(Y_sklearn[y==lab, 0],  
                    Y_sklearn[y==lab, 1],  
                    label=lab,  
                    c=col)  
    plt.xlabel('Principal Component 1')  
    plt.ylabel('Principal Component 2')  
    plt.legend(loc='lower center')  
    plt.tight_layout()  
    plt.show()
```

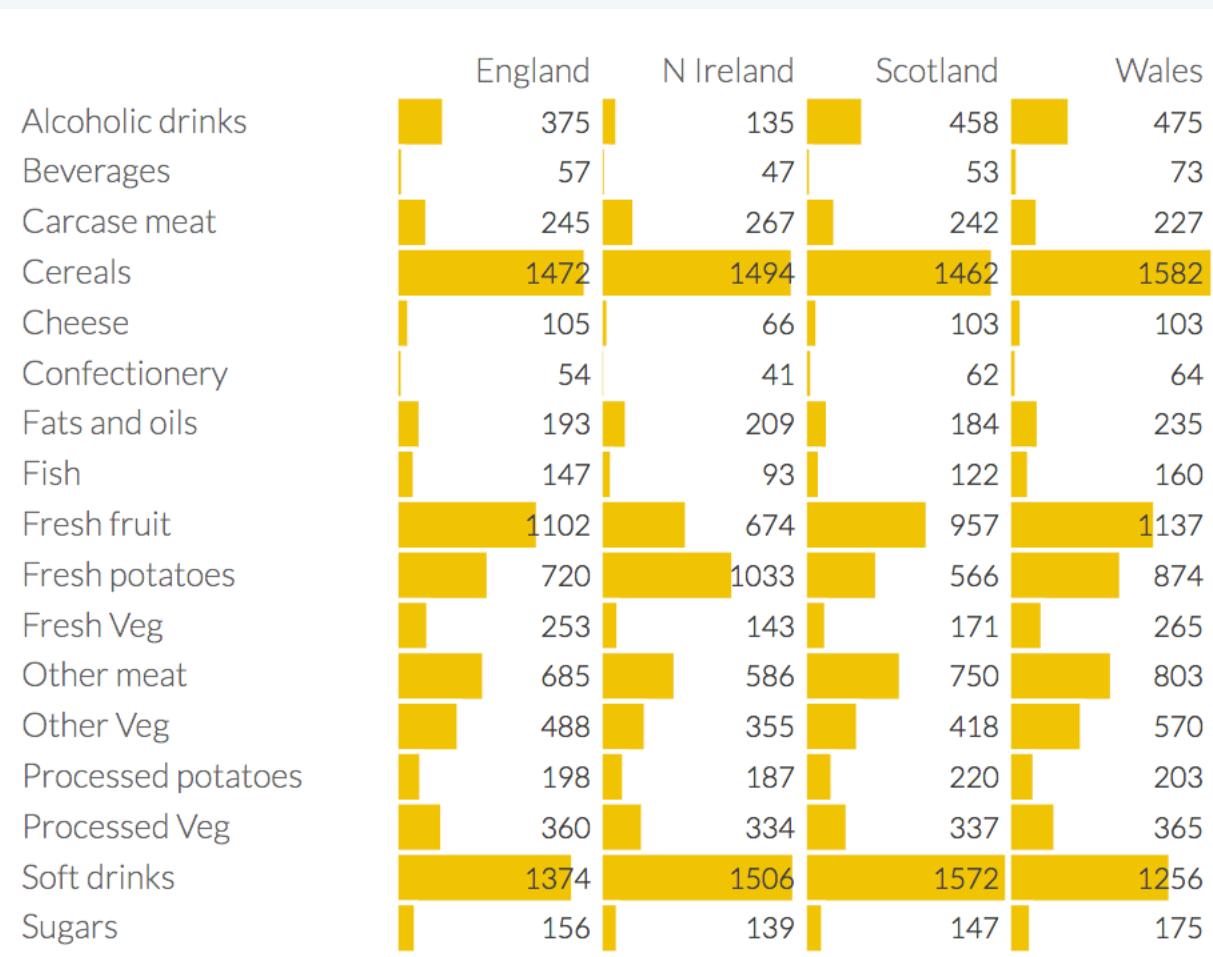

scikit-learn

Machine Learning in Python

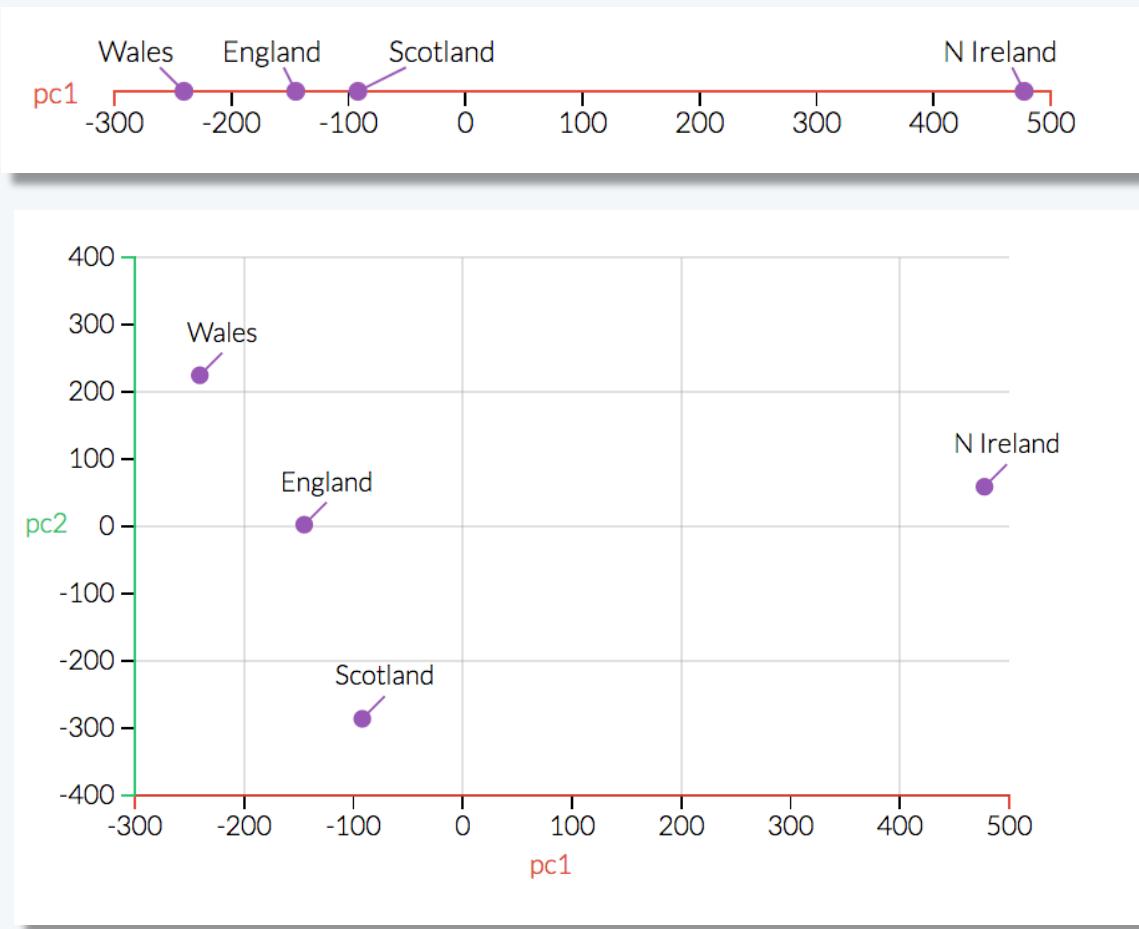

- Simple and efficient tools for data mining and data analysis
- Accessible to everybody, and reusable in various contexts
- Built on NumPy, SciPy, and matplotlib
- Open source, commercially usable - BSD license

<https://scikit-learn.org/>

Eating in the UK (a 17d example)

1d and 2d Score Plot:

Northern Irish eat way more grams of fresh potatoes and way fewer of fresh fruits, cheese, fish and alcoholic drinks.

PCA on pictures. Let's start with 64x64 dimensions.

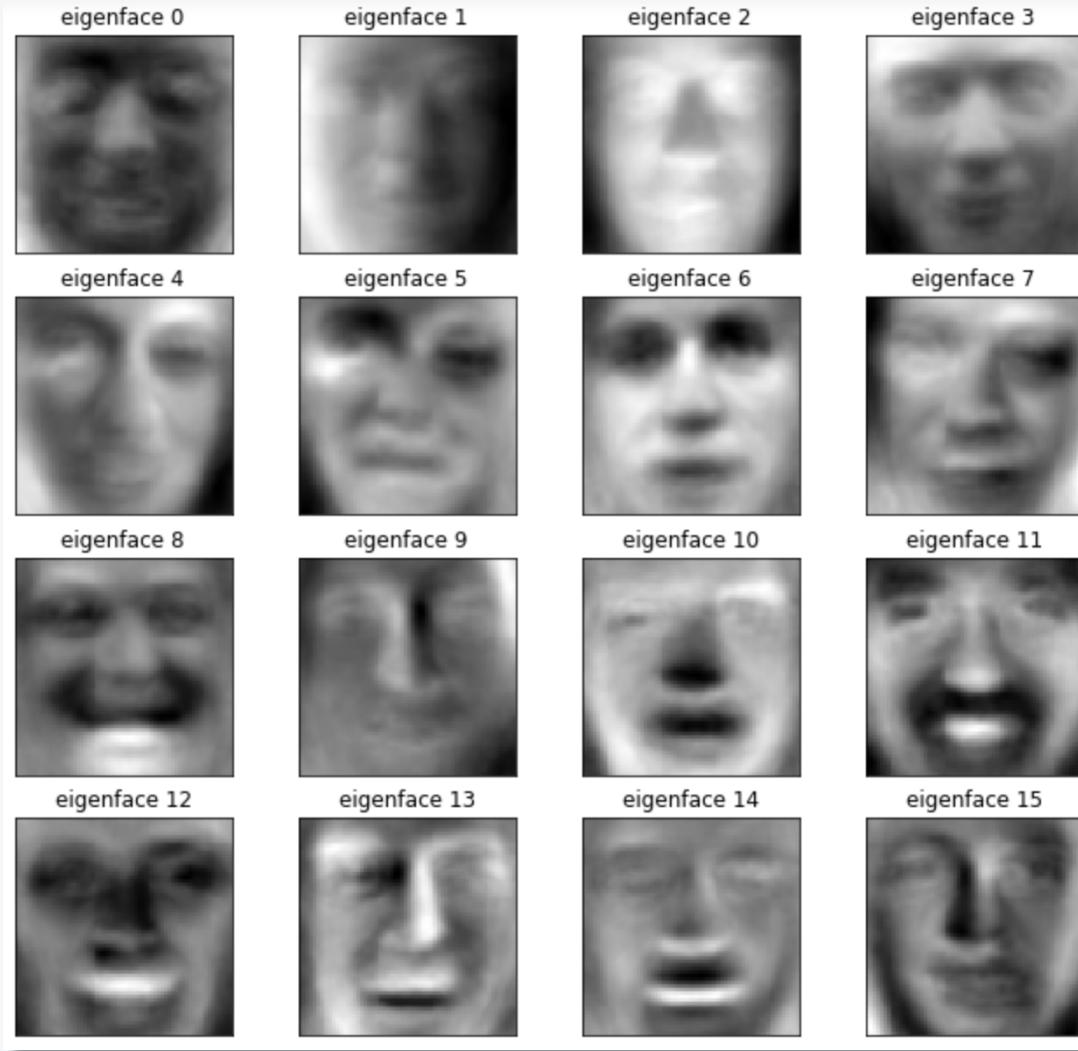

1. Obtain images
2. Represent every image as vector
3. Compute the average face
4. Subtract the average face
5. Compute the covariance matrix
6. Use a SVD decomposition / computation of eigenvectors
7. Project picture into eigenface-space and measure distance

We will use OpenCV (via Python bindings)

OpenCV (Open Source Computer Vision Library) is an open source computer vision and machine learning software library. <https://opencv.org/>

Eigenfaces (eigenvectors / principal components, visualized)

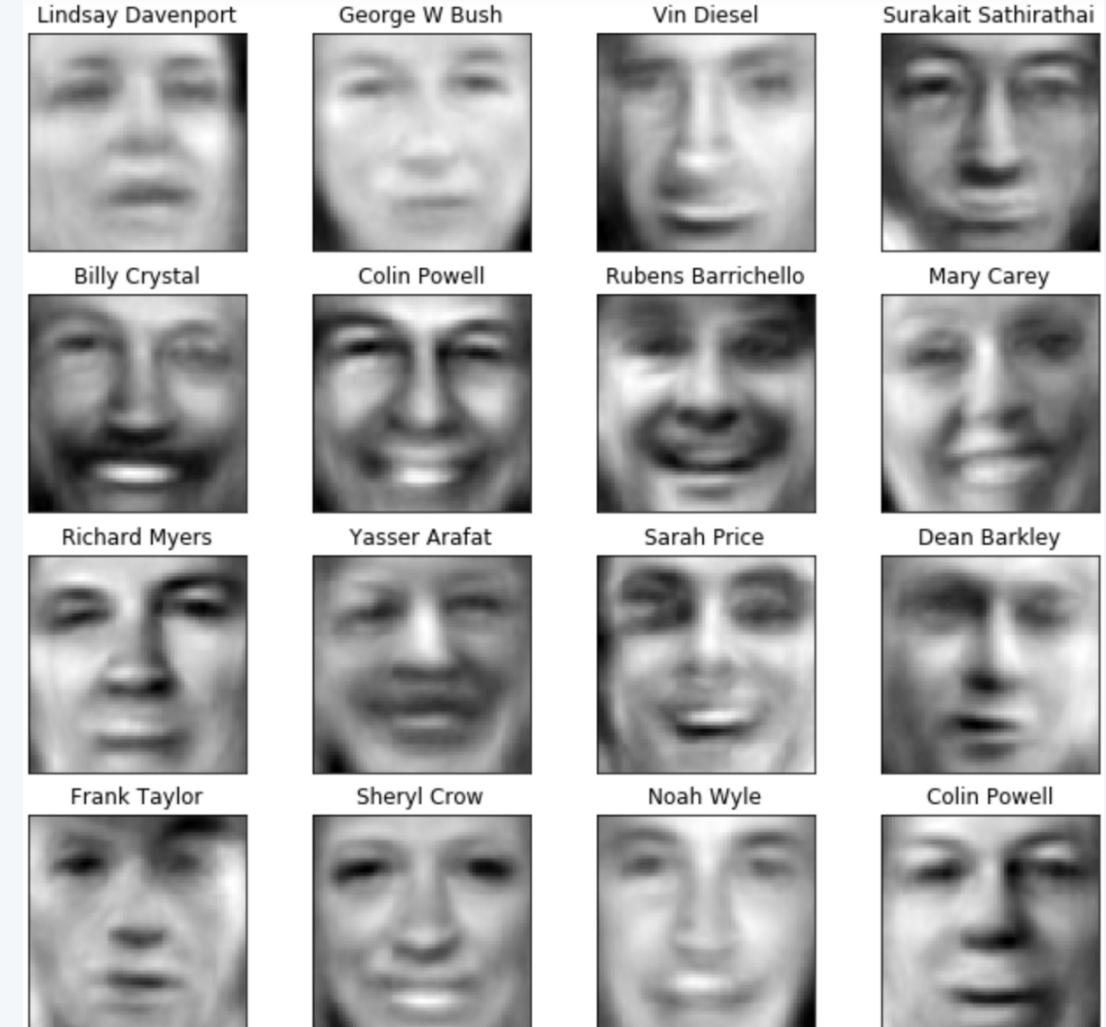

$$\text{Face Image} = 0.3845^* \text{ eigenface 0} - 0.5435^* \text{ eigenface 1} + 0.0345^* \text{ eigenface 2} - 0.74645^* \text{ eigenface 3} + \dots$$

Using n=50 principal components

Original

Weighted combination of n eigenfaces

Using n=100 principal components

Original

Weighted combination of n eigenfaces

Using n=250 principal components

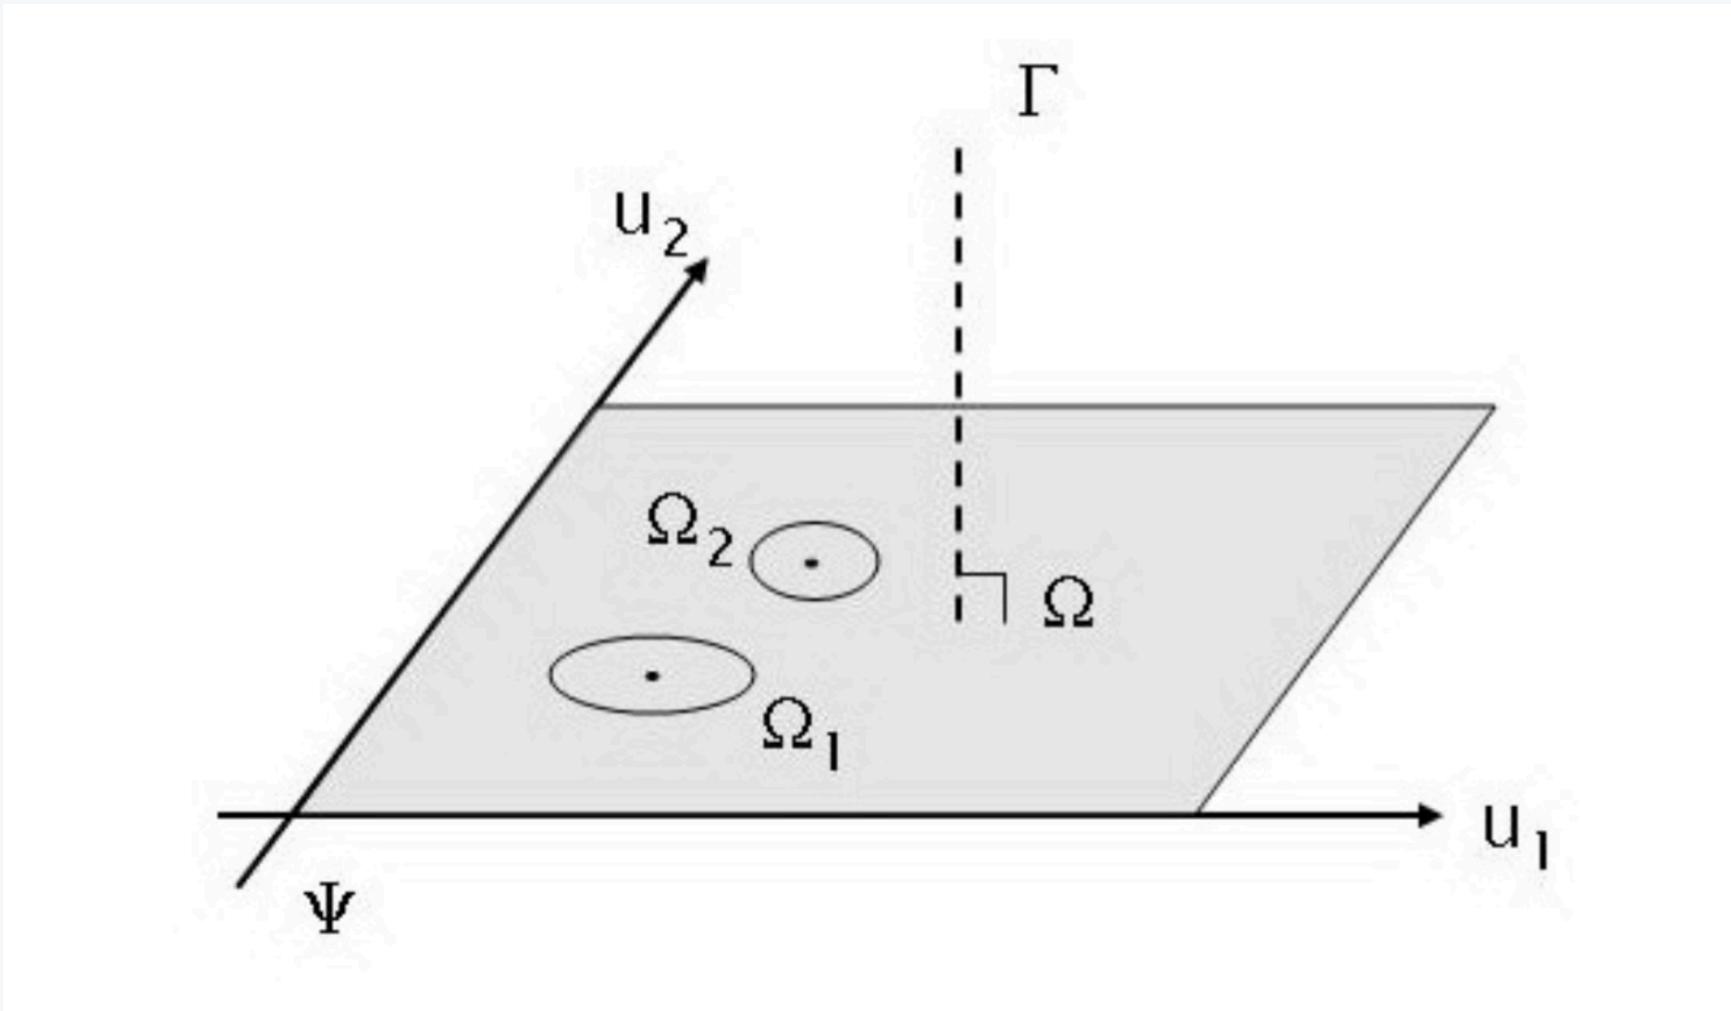

Original

Weighted combination of n eigenfaces

Eigenface space: origin is the average face, and axes are the eigenfaces.

Projection onto eigenface space.

...and using the distance to the eigenface space for classification

PCA::project

Projects vector(s) to the principal component subspace.

C++: Mat `PCA::project(InputArray vec)` const

1

C++: void `PCA::project(InputArray vec, OutputArray result)` const

Python: `cv2.PCAProject(data, mean, eigenvectors[, result]) → result`

Parameters:

- **vec** – input vector(s); must have the same dimensionality and the same layout as the input data used at PCA phase, that is, if `CV_PCA_DATA_AS_ROW` are specified, then `vec.cols==data.cols` (vector dimensionality) and `vec.rows` is the number of vectors to project, and the same is true for the `CV_PCA_DATA_AS_COL` case.
- **result** – output vectors; in case of `CV_PCA_DATA_AS_COL`, the output matrix has as many columns as the number of input vectors, this means that `result.cols==vec.cols` and the number of rows match the number of principal components (for example, `maxComponents` parameter passed to the constructor).

The methods project one or more vectors to the principal component subspace, where each vector projection is represented by coefficients in the principal component basis. The first form of the method returns the matrix that the second form writes to the result. So the first form can be used as a part of expression while the second form can be more efficient in a processing loop.

PCA::backProject

Reconstructs vectors from their PC projections.

C++: Mat `PCA::backProject(InputArray vec)` const

C++: void `PCA::backProject(InputArray vec, OutputArray result)` const

Python: `cv2.PCABackProject(data, mean, eigenvectors[, result]) → result`

- Parameters:**
- **vec** – coordinates of the vectors in the principal component subspace, the layout and size are the same as of `PCA::project` output vectors.
 - **result** – reconstructed vectors; the layout and size are the same as of `PCA::project` input vectors.

The methods are inverse operations to `PCA::project()`. They take PC coordinates of projected vectors and reconstruct the original vectors. Unless all the principal components have been retained, the reconstructed vectors are different from the originals. But typically, the difference is small if the number of components is large enough (but still much smaller than the original vector dimensionality). As a result, PCA is used.

Example, using a 10 dimensional eigenface space:

```
In [16]: i=(data[0,:])  
  
In [17]: result=cv2.PCAProject(i,mean.reshape(i.shape),eigenVectors)  
  
In [18]: i.shape  
Out[18]: (96768,)  
  
In [19]: result  
Out[19]:  
array([[ 36.499718],  
       [ 24.19416 ],  
       [-16.804926],  
       [-31.866632],  
       [-25.335268],  
       [ -7.799864],  
       [ -5.968835],  
       [ 11.209648],  
       [-22.533894],  
       [-16.296684]], dtype=float32)
```

Note: each picture is represented with 10, instead of 96768 numbers (but of course there is quality loss)

Back projection:

```
In [21]: pic=cv2.PCABackProject(result, mean.reshape(i.shape), eigenVectors).reshape(sz)  
  
In [22]: pic.shape  
Out[22]: (192, 168, 3)
```

Which was the dog?

Conclusion

- PCA: a **very important statistical procedure** (some might say machine learning method) for dimensionality.
- Revealing the **internal structure of the data** in a way that best explains the variance in the data.
- Used in (as such or as a basis for) a **whole range of application scenarios**, such as stock market predictions, the analysis of gene expression data, neuroscience, chemical compound analysis, and many many more.
